TECHNICAL FIELD

[0001] The present invention relates to a method and system for generating random numbers with a specified probability density function that is faster and more efficient than current methods and system.

BACKGROUND OF THE INVENTION

[0002] Methods for generating random numbers with a specified probability density function (PDF) are well known. One such method is the Monte Carlo Method. The Monte Carlo method provides approximate solutions to a variety of mathematical problems by performing statistical sampling experiments on a computer. The method applies to problems with no probabilistic content as well as to those with inherent probabilistic structure.

[0003] While the conventional Monte Carlo method is often an acceptable sampling method, it is typically accurate only after it has converged in statistics. This convergence can take a very large number of random samples to provide the desired accuracy. For example, a simulator utilizing the Monte Carlo method may include many loops (for example, "For Loops" would be used in C), nested or otherwise, to generate an accurate statistical sample with multiple random variables. Running such loops with the many iterations can take hours or days, depending on the speed of the computer or processor. Further, the amount of time may increase more than linearly with the number of samples or the number of loops required to achieve convergence. Effective random-number generation is therefore desirable.

[0004] Other prior techniques for generating random numbers with a specified PDF utilized "brute force." For example, a random number sequence uniformly distributed between 0 and 1 was first generated by calling on known system-provided routines. One difficulty with this approach is that it can take a very large amount of data before a sufficiently uniform distribution is realized depending upon application requirements. In cases where non-uniformly distributed random numbers are required, a controlled mapping was typically implemented in a conventional way to "shape" the numbers with the desired PDF. This could be done, for example, by building a lookup table, again with a brute-force mapping. This again can be extremely time consuming.

[0005] Thus, it would be desirable to provide a random number generation method that is quicker than prior methods and also reduces the number of samples that must be generated to achieve the desired statistical accuracy.

SUMMARY OF THE INVENTION

[0006] It is therefore an object of the present invention to provide a random number generation method and system that requires less time than prior methods.

[0007] It is a further object of the present invention to provide a random number method that reduces the number of samples needed to obtain a given overall accuracy for low-occurrence events.

[0008] It is still another object of the present invention to provide a random number generation system that is both systematic and efficient.

[0009] In accordance with the above and other objects of the present invention, a random number generation having a cumulative density function (CDF) is provided. (The CDF is the integral of the PDF). According to the method, a set of discrete

numbers between an upper limit and a lower limit is generated. The set of discrete numbers are uniformly spaced between the upper limit and the lower limit. Each individual number from the set of random numbers is mapped to a corresponding value on a cumulative density function curve to provide a number of samples. The samples are then scrambled to randomize the order of the samples.

[0010] As an additional step, the number of samples can be subjected to companding in certain applications. The step of companding helps provide a sufficient representation of a low-probability area, while decreasing the total number of samples.

[0011] These and other features and advantages of the present invention will become apparent from the following description of the invention, when viewed in accordance with the accompanying drawings and appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] Figure 1 is a graph schematically illustrating the mapping of uniform random numbers to generate a given cumulative density function in accordance with a preferred embodiment of the present invention;

[0013] Figure 2 is a graph schematically illustrating the identification of a low-probability area of the CDF for companding in accordance with a preferred embodiment of the present invention;

[0014] Figure 3 is a flow chart schematically illustrating the sequence and operation of a random number generation system and method in accordance with a preferred embodiment of the present invention;

- [0015]** Figure 4(a) is a graph illustrating a sample without companding;
- [0016]** Figure 4(b) is a graph illustrating a sample with companding; and
- [0017]** Figure 5 is a flow chart schematically illustrating the sequence and operation of an exemplary application of a random number generation system and method in accordance with a preferred embodiment of the present invention.

BRIEF DESCRIPTION OF THE PREFERRED EMBODIMENT

[0018] The present invention is intended to allow random numbers of any distribution to be generated, such as through Monte Carlo simulation, in a significantly reduced period of time as compared to prior systems and methods. The disclosed system may be used in a lab environment with general purpose computers or may alternatively be implemented in commercial products with special-purpose processors. Moreover, the present invention may be utilized for a variety of applications for which random number generation is or can be used.

[0019] Referring now to the Figures and specifically Figure 3, the preferred system and method 10 is preferably comprised of three components. The first component is an initial sample generation component 12, which generates numbers with immediate uniform distribution. In accordance with the number generation component 12, a set of numbers $\{R\}$ is generated. The set of random numbers is preferably generated such that they have a uniform distribution between 0 and 1. Equivalently, instead of a uniform distribution between 0 and 1, random percentages may be generated to have a uniform distribution between 0% and 100%.

[0020] The first component of the invention, as generally indicated by reference number 12, improves distribution of random numbers by generating evenly spaced values for $\{Y\}$ between 0 and 1. This process provides a uniform

representation across the interval of $[0, 1]$. It gives a smooth appearance to performance curves compiled from processing random numbers. With conventional generation methods, it would take a much larger number of samples to achieve the same curve smoothness. Alternatively, instead of generating random uniform samples for $\{R\}$, R can be replaced with an evenly spaced set of values $\{Y\}$. This provides a curve with an even smoother appearance.

[0021] In the second component of the invention, shown by reference number 14 of Figure 3, thereafter, a set of values $\{X\}$ are generated in ascending order with a specified PDF and a corresponding set of descending CDF values. This is accomplished through a lookup table listing X vs. Y values on the CDF curve, an illustrative example of which is shown in Figure 1. The designator X is a random number with a CDF Y , and $Y(X)$ is the probability that a randomly selected number from the set will be greater than or equal to X . In order to look-up the X value for a given input value R_i in $\{R\}$, the conventional concept is to compare the randomly quantified number R_i with members of $\{Y\}$ to find the closest discrete value Y_k to R_i and therefore the corresponding value X_k . In other words, a value in the random set source set $\{R\}$ is selected and mapped or looked-up on the CDF curve/table to determine the corresponding value. This process is repeated with each member of $\{R\}$ to get a set of numbers with the specified CDF.

[0022] As shown in Figure 1, the CDF starts with a numerical value of 1.0 and decreases to 0. (For our convenience and without loss of generality, this ascending order of the CDF is reversed from the normal convention, which has a CDF beginning at 0 and increasing to a numerical value of 1). By arranging $\{R\}$ in a monotonic order, as automatically provided by component 12, the process of comparing R_i to each sequential member of $\{Y\}$, beginning at Y_1 , can stop at the first value Y_k which

is found to be less than R_i . This process would then be repeated for every member in $\{R\}$.

[0023] The preferred method provides a more efficient way to look up the X value for each input element in $\{R\}$. Initially, all values of $\{R\}$ are arranged in, say, a descending order. Since both $\{Y\}$ and $\{R\}$ are in descending order, it would not be necessary to begin at Y_1 each time to find the nearest value in $\{Y\}$. Since the next value of R , R_{k+1} , is smaller than R_k , Y_{k+1} is smaller or equal to Y_k . In fact, Y_{k+1} is very close to Y_k , and the search becomes very fast. Since significantly few comparisons with candidate numbers are required, significant overall savings in processing can be achieved through utilization of the disclosed method and system. After the lookup has been completed, the order of $\{X\}$ values are scrambled, as generally indicated by reference number 16. Order randomization may be achieved in one of several ways. For example, it may be done by generating a pseudo-random number (PRN) sequence $\{P\}$, which is then truncated to the length of $\{X\}$ if necessary. $\{X\}$ is then reordered by the elements of $\{P\}$ as the latter are generated one at a time.

[0024] The first and second components of the invention may be combined as follows. First, $\{R\}$ is generated by uniform stepping between 1 and 0 in descending order. The $\{X\}$ values are then generated in ascending order with table lookup. The lookup process proceeds without the need for pre-sorting $\{R\}$. As set forth above, at the end of lookup, the $\{X\}$ values are then scrambled. Again, scrambling is systematic and is more efficient than the brute force comparison, discussed above.

[0025] The third component of the invention, as generally indicated by reference number 18, is the companding component. In many applications, the companding improves the representation of certain regions of interest on the PDF.

This concept is particularly useful for PDFs where a section of interest has a much lower probability. This means that very few points are generated in this region by the conventional method, which therefore requires a much larger number of experiment samples to guarantee a sufficient representation of the low probability section. As the required members of samples increased, the run-time may increase even more rapidly. At the same time, more than enough samples are generated for the high probability areas of the PDF and are thus “wasted.” Thus, the companding component increases the representation of low-probability samples without increasing the representation high-probability samples.

[0026] For example, a given PDF might have 90% of its events happening between A and B in Figure 2, but only 10% between B and C. Suppose the impact of interest is from the scarce region between B and C. For each sample generated between B and C as desired, 9 samples between A and B would normally be generated as well. This is where the method of companding comes in. With companding, 10 times as many random points $\{R\}$ would be generated between 0 and 0.1 of Y, as would normally be generated. This is accompanied with a corresponding reduction in the number of samples generated between the popular region between 0.1 and 1.0 of Y for a given member of total samples. After all the points are generated and statistically processed, the over-represented section is re-adjusted by dividing the probability of that section by the companding factor N. Therefore, the low-probability samples are compressed while the high-probability samples are expanded. In effect, by reducing the spacing for low probability samples, more samples are present in the low-probability area. By increasing the spacing for the high probability area, fewer samples are present in the high-probability area.

[0027] Figures 4(a) and 4(b) illustrate two exemplary graphs (with CDF slopes in the conventional sense). Figure 4(a) illustrates a sample generation without companding (Y sampling uniformly spaced). Figure 4(b) illustrates a sample with companding. As shown by comparison of the Figures, the distribution of the samples provides a more accurate representation of the low-probability curve.

[0028] The combination of these three components provide a very efficient and accurate method and system for generating a set of random number with a given PDF.

[0029] Turn now to Figure 5, which illustrates an exemplary application for the disclosed method and system. Preferred applications for the present invention include an impact analysis of rain and interference on satellite service availability. More specifically, this application allows a more thorough statistical link budget analysis when multiple statistical parameters must be analyzed. This has not previously been performed due to the huge amount of simulation that would be required to simulate interactions of the various parameters. By making such simulations feasible, the disclosed method can allow a more accurate link budget and provides better knowledge about a given system's capabilities, all with manageable computer processing time. By obtaining the total system performance statistics, worst case assumptions can be minimized. This will allow a more balanced design for optimal system performance within the limits of all resources.

[0030] Referring specifically to Figure 5, rain and interference have been typically constant in past analysis, but can now be time varying. Thus, to determine the total impact of rain and interference, they can be combined in a Monte Carlo fashion. Initially, the parameter values from the link budget are obtained, as generally indicated by reference number 30. Thereafter, lookup tables for rain and interference

impact CDFs are built, as generally indicated by reference number 32, based on a variety of factors, as will be appreciated by one of skill in the art.

[0031] Companded rain and/or an interference samples can then be generated based on the look-up tables, as generally indicated by reference number 34. Degradation histograms (PDFs) from rain with and without interference are then formed, as generally indicated by reference number 36. The histograms for these two cases are normalized for companding, as generally indicated by reference number 38. The threshold of clear sky (CS) margin is then determined at 40. Finally, the change in availability due to interference can then be determined, as generally indicated by reference number 42.

[0032] Having now fully described the invention, it will be apparent to one of ordinary skill in the art that many changes and modifications can be made thereto without departing from the spirit or scope of the invention as set forth herein.
